

THRESHOLD CONDITIONS EMERGING POPULATION ATTRITION PHYSICAL CONTROL DOCUMENTATION POSTURE

A. Coverage and Accuracy Following Facility Change

The distinction between HUBZone-designated contractors in Nevada whose Active FCI Posture Record coverage reflects the physical protection domain as it currently exists and those whose records carry a verified description of a prior facility configuration defines the population-level documentation condition observed through prime contractor supply chain review infrastructure operating across this contracting environment. Among contractors at equivalent revenue thresholds in comparable procurement environments, the proportion whose physical protection documentation has been verified against the current facility configuration falls below what review processes observe in peer populations that have not undergone recent relocation. The record carries the current environment or it does not. For HUBZone contractors in Nevada whose facility address has changed, it does not, at a rate that positions this population below the coverage threshold observed in comparable certification classes under DFARS 252.204-7012 continuous documentation requirements.

Both findings remain unresolved within the same documentation period: the organization holds an active HUBZone designation tied to a physical location, and the physical protection documentation within the Active FCI Posture Record describes a facility the organization no longer occupies. The record is a record that carries a boundary description that predates the current assessment period.

B. Emerging Attrition in Record Accuracy

The accuracy of physical control documentation among this population erodes as the interval between relocation and record confirmation lengthens, and relative to contractors at equivalent revenue thresholds in comparable procurement environments that have not relocated, the emerging attrition in record accuracy positions the HUBZone Nevada population further from the verified state with each assessment cycle that passes without confirmation. The record is aligned with the current configuration or it is not aligned with it. Documentation that describes visitor access protocols, physical access controls, and media protection procedures for a facility the organization vacated addresses a configuration the organization no longer maintains. The two states are simultaneously observable in the

record: a verified attestation exists, and the environment it describes does not.

Against what supply chain review activity observes in peer certification populations at the same threshold, the gap and the posture share the same observation point. The record coverage does not extend to the current facility. The record accuracy does not reflect the current physical control environment. The result is a record that addresses the boundary as it existed before the triggering event. The condition is present. The emerging attrition across this population continues without resolution within the current assessment cycle.
